## Problem 1 – Lexical Scoping Code Generation

Assume that all variables are lexically scoped.

```
program main()
{
  int a, b;
  procedure f()
  {
    int c;
    procedure g()
    {
      ... = b + c    //<<<----- (*A*)
      print a,b,c;
    end g;
  }
  a = 0; c = 1;
  ... = b + c    //<<<----- (*B*)
  call g();
  print c;
end f;
}
procedure g()
{
  int a,b;
  a = 3; b = 7;
  call f();
  print a,b;
end g;
}
a = 2; b = 3;
print a,b;
call g();
print a,b;
end main;
}
```

1. Show the runtime stack with its stack frames, access and control links, and local variables when the execution reaches program point (\*A\*).

2. Give the ILOC RISC code for the expressions at program points (\*A\*) and (\*B\*). The value of the expressions need to be loaded into a register. The particular register numbers are not important here.

## Problem 2 – Parameter Passing

```

program foo()
{
    a, b integer;
    procedure bar(integer x, integer y)
    {
        z: integer;
        <----- /* 0 */
        z = 3;           /* 1 */
        x = x + y + z;   /* 2 */
        y = 1;           /* 3 */
    }
    // statement body of foo
    a = 2;
    b = 5;
    call bar(a, b);
    print a, b; }

```

Use the RISC machine instructions `load`, `loadI`, `loadAI`, `storeAI`, `add` to show the code that needs to be generated for the body of procedure `bar` (statements `/*1*/` through `/*3*/`). Assume that

1. Register `r0` contains the frame pointer (`fp`) value.
2. Formal parameter `x` is **call-by-reference**, and formal parameter `y` is **call-by-value**. Assume that `bar`'s parameters `x` and `y` have been correctly initialized as part of the procedure call of `bar`.
3. Use the stack frame layout as shown above. The figure shows the runtime stack when the program execution reaches program point `/*0*/` in procedure `bar`.

What values for `a` and `b` does the program print?

## Problem 3 – Parameter Passing

Assume that you don't know what particular parameter passing style a programming language is using. In order to find out, you are asked to write a short test program that will print a different output depending on whether a *call-by-value*, *call-by-reference*, or *call-by-value-result* parameter passing style is used. Your test program must have the following form:

```
program main()
{
    a integer;
    procedure foo(integer x)
    {
        // statement body of foo
    }

    // statement body of main
    a = 1;
    call foo(a);
    print a;
}
```

The body of procedure *foo* must only contain assignment statements. For instance, you are not allowed to add any new variable declarations.

1. Write the body of procedure *foo* such that **print a** in the **main** program will print different values for the different parameter passing styles.
2. Give the output of your test program and explain why your solution works.
